

Non CNN example-Skeleton

March 2, 2025

This example is similar to, although not identical to, examples given in Chapter 2 of the book [Deep Learning with Python, Second Edition](#).

1 Non CNN fully connected network

This first example looks at generating a simple fully connected network. Its function is both to investigate the network topology and its abilities but also to (re-)familiarise you with how to construct such a network in KERAS.

This example will use the functional API components of KERAS which is more flexible than the Sequential API employed in COMP8270 although hopefully will not prove more challenging to learn.

The network will again use a character recognition task but this time using greyscaled numerals as found in the standard MNIST dataset. This first cell loads this dataset for us to use.

```
[1]: import tensorflow as tf

tf.__version__

```

```
[1]: '2.14.0'
```

```
[2]: from tensorflow.keras.datasets import mnist

(train_images, train_labels), (test_images, test_labels) = mnist.load_data()
```

Note the images consist of 28 x 28 pixels each. There are 60000 training images.

```
[3]: train_images.shape
```

```
[3]: (60000, 28, 28)
```

2 Defining the network architecture

This is the first section you need to write yourselves.

The workshop script takes you through what you need to do. Note the **Inputs** are defined for you however. Your function is to fill in the missing sections to define the layers you will need to employ.

Note the section concludes by printing out of summary of the model that has been defined.

```
[4]: from tensorflow import keras
from tensorflow.keras import layers

inputs = keras.Input(shape=(28 * 28)) # 28 x 28 grey scaled images

first = layers.Dense(784, activation="sigmoid")(inputs)
second = layers.Dense(784, activation="sigmoid")(first)
outputs = layers.Dense(10, activation="softmax")(second) # 10 output classes

model = keras.Model(inputs=inputs, outputs=outputs)

model.summary()
```

Model: "model"

Layer (type)	Output Shape	Param #
input_1 (InputLayer)	[(None, 784)]	0
dense (Dense)	(None, 784)	615440
dense_1 (Dense)	(None, 784)	615440
dense_2 (Dense)	(None, 10)	7850

Total params: 1238730 (4.73 MB)
 Trainable params: 1238730 (4.73 MB)
 Non-trainable params: 0 (0.00 Byte)

3 Compiling the model

The next stage is to compile the model using an optimiser and an error calculation. Follow the script to deduce what to put here.

```
[5]: model.compile(optimizer="adam",  
                  loss="sparse_categorical_crossentropy",  
                  metrics=["accuracy"])
```

Preparing the image data

This cell prepares the image data for presentation to the network. It is provided for you although you should examine it to ensure you understand its function.

It essentially reformats the input image to be a flat vector of pixel values with values ranging from 0 to 255.

```
[6]: train_images = train_images.reshape((60000, 28 * 28))  
train_images = train_images.astype("float32") / 255  
test_images = test_images.reshape((10000, 28 * 28))  
test_images = test_images.astype("float32") / 255
```

4 Training the model

To define this sections, the number of epochs need to be selected together with the batch size, the training algorithm itself has already been selected by the **compile** method but the call to the **fit** method actually performs the training.

```
[7]: print("Train images shape:", train_images.shape) # (60000, 784)  
print("Test images shape:", test_images.shape) # (10000, 784)
```

Train images shape: (60000, 784)

Test images shape: (10000, 784)

```
[8]: model.fit(train_images, train_labels, epochs=5, batch_size=32,  
              ↪validation_data=(test_images, test_labels))
```

Epoch 1/5

1875/1875 [=====] - 31s 16ms/step - loss: 0.3292 -
accuracy: 0.9013 - val_loss: 0.1823 - val_accuracy: 0.9426

Epoch 2/5

1875/1875 [=====] - 28s 15ms/step - loss: 0.1334 -
accuracy: 0.9598 - val_loss: 0.1016 - val_accuracy: 0.9674

Epoch 3/5

1875/1875 [=====] - 28s 15ms/step - loss: 0.0846 -
accuracy: 0.9732 - val_loss: 0.0848 - val_accuracy: 0.9749

Epoch 4/5

```
1875/1875 [=====] - 28s 15ms/step - loss: 0.0583 -  
accuracy: 0.9811 - val_loss: 0.0718 - val_accuracy: 0.9772  
Epoch 5/5  
1875/1875 [=====] - 27s 14ms/step - loss: 0.0420 -  
accuracy: 0.9865 - val_loss: 0.0639 - val_accuracy: 0.9802
```

```

```

5 testing the network

The following prints out the probability outputs that arise in the final layer. Change the range of test images to investigate different images

Each element in the **predictions** array represents the result for a given test pattern

```
[9]: test_digits = test_images[0:10]  
predictions = model.predict(test_digits)  
predictions[0]
```

```
1/1 [=====] - 0s 123ms/step
```

```
[9]: array([9.9463897e-08, 7.8158200e-07, 2.4941264e-06, 2.6641439e-05,  
          8.6344470e-10, 6.7925754e-07, 2.9656325e-12, 9.9996108e-01,  
          3.9186173e-08, 8.2140286e-06], dtype=float32)
```

```
[10]: predictions[0].argmax()
```

```
[10]: 7
```

The **evaluate** method provides metric values for the entire test set

```
[11]: test_loss, test_acc = model.evaluate(test_images, test_labels)  
print(f"test_acc: {test_acc}")
```

```
313/313 [=====] - 2s 6ms/step - loss: 0.0639 -  
accuracy: 0.9802  
test_acc: 0.9801999926567078
```
